complexity usually grows exponentially with the number of rounds, ensuring that such attacks become rapidly impractical. In contrast, algebraic attacks exploit the intrinsic algebraic structure of a cipher. More specifically, the attacker expresses the encryption transformation as a (large) set of multivariate polyno-

describing the complexity of GAN sample spaces (Khruikov & Oseledets, 2018). More precisely, we rephrase deep networks with fully-connected layers into the language of algebraic topology and develop a measure for assessing the structural complexity of i) individual layers, and ii) the entire network. In this work, we present the following ...
